

Content service

The content service is used for creating text elements in for example pages. It contains a wysiwyg ('what you see is what you get') editor and contains many functions to create rich content.

Font functions

Font functions enable a content manager to apply font styles like bold, italic, underlined, tabs, bullets and lists.

Linking functions

Create internal and internal managed links. Managed links are tested existence, every night a report is generated listing all broken links to external sites and other sources.

Wrapped functions

The content can be wrapped around other Xsdot services and components.

Filter functions

When copy pasting content from other web sites or text editors like Microsoft Word the content many times has wrong and unsupported html code. The content service filters non xhtml standard code to ensure technically correct web sites.
